

Achieving Autonomous Operations

An end-user focused approach and maturity model by WIB/NAMUR

#autonomous plants #ai #process industries

The level of autonomous operation of a plant can be described by the so called "Autonomous Operation Maturity Levels". These levels range from 0 (all manual) to 5 (full autonomous operation). This contribution gives guidelines to assess the maturity level of existing plants and identify necessary tools, hardware and programs to achieve the next level of autonomy. This is summarized in three matrices for the following categories: Asset Management, Process Management, and Production Management.

Der Grad des autonomen Betriebs einer Anlage kann durch die so genannten „Autonomous Operation Maturity Levels“ beschrieben werden. Diese Stufen reichen von 0 (vollständig manueller Betrieb) bis 5 (vollständig autonomer Betrieb). Dieser Beitrag beschreibt Leitlinien zur Bewertung des Reifegrads bestehender Anlagen und zur Ermittlung der erforderlichen Werkzeuge, Hardware und Programme, um die nächste Stufe der Autonomie zu erreichen. Dies wird in drei Matrizen für die folgenden Kategorien zusammengefasst: Anlagenmanagement, Prozessmanagement und Produktionsmanagement.

1. Introduction

The future will confront process industries with major challenges. Among these are increasing productivity and demand for more sustainability in all regions, greater flexibility in production and business processes, demographic changes, and the availability of experts in growth markets. Optimizing operational models by implementing automation and digital technologies is one of the most fundamental possibilities to cope with these challenges, provided that the human element is properly considered as well.

Remote and autonomous operation (AO) concepts for plants provide a way to face these challenges. To achieve the economic goals associated with remote and autonomous operation, technological, human, social, and legal aspects need to be considered. Compromises on safety aspects are neither acceptable nor necessary since the respective technologies also offer potential to enhance process stability and surveillance.

NAMUR has published Recommendation NE 161 "Remote Operation Basics" [1] in 2016, suggesting three autonomy levels. In 2020, ARC [2] published an Autonomous Operations Maturity Model. The level of autonomous operation of a plant is described by the so called "Autonomous Operation Maturity Levels". This model suggests using level 0 as non-autonomous plant and levels 1 to 5 defining higher levels of automation (levels 1 and 2) and autonomy (levels 3 to 5). ARC describes the levels in a general form but gives no specific information for the implementation of the levels.

WIB's "Autonomous Operations Working Group" and NAMUR's WG 4.20 "Remote and Autonomous Operation"

Figure 1: Categories for Autonomous Operation.

went to the details for three categories needed for Autonomous Operation:

- Asset Management
- Process Management
- Production Management.

For each Category, an “Autonomous Operation Maturity Matrix” (AOM Matrix) has been created. This paper describes the concept of these matrices.

2. Autonomous Operation Maturity Levels

This paper is based on maturity definitions (5 levels) as proposed by ARC [1], but we have redefined, refined and extended these definitions. A clear state definition for each maturity level and a common understanding is key. The levels 1 & 2 are deemed foundational and are not considered. To establish the foundation for our AOM Matrix, levels 3, 4 and 5 have been interpreted as follows:

- **Level 3 “Advanced Regulatory / Predictive”:** Selected process units are semi-autonomous, human interventions are required when outside defined operating conditions.
- **Level 4 “Select Autonomy / Prescriptive”:** Selected process units are autonomous between planned shutdowns that allow for replacements, upgrades and expansions. Human interactions are limited to non- or semi-autonomous process units. Unexpected shut-

downs due to equipment breakdown are exceptional and minimized.

- **Level 5 “Autonomous”:** All process units are autonomous between planned shutdowns that allow for replacements, upgrades, and expansions. Human interactions are maintenance-centered during planned shutdowns. There are no unexpected plant stops due to equipment breakdown. Where Process, Production and Asset Management is still essential within the context of autonomous plant operation at this level, they are largely merged and have become part of an integrated organization.

3. Categories to be covered for Autonomous Operation

For an Autonomous Operation, three Categories have to be covered:

- **Asset Management:** Each level of AO has requirements for the plant assets to enable this Operation. Assets must be designed and managed to fulfill these requirements.
- **Process Management:** Similarly, AO requires an appropriate process management for each AOM level.
- **Production Management:** Also, the production management must provide all relevant services and information needed for the levels.

Supply chain-related topics within the scope of the matrix are assigned to the

Production Management domain. Consequently, the matrix does not cover Supply Chain Management functions at the business level (typically managed in ERP systems). Instead, it focuses on translating business needs (such as production requirements, resource tracking, planning, and scheduling) into appropriate functions at the plant level, orchestrated by Production Management. Figure 1 illustrates this graphically.

4. The Autonomous Operations Maturity Matrices

For each of the categories mentioned in section 3, an AOM Matrix has been created. This section describes the rows and the columns of these matrices.

4.1 Vertical dimension of the AOM Matrices

The vertical dimension displays all swim lanes with their respective states and transitions, as outlined in Figure 2, which provides an overview of the table of contents for the three categories Asset Management, Process Management and Production Management. E.g., Asset Management includes Design of equipment, Measurability of asset properties, Condition monitoring, Maintenance Strategy and Execution and IT/OT foundations. Each of these topics consists of 3 to 5 sub-topics as shown in the last column of Figure 2.

Autonomous Operations Working Group		
Framework document		
Version: 2.0		
Date: 30 October 2023		
Back to coversheet		Link to Level Definitions
		Link to Abbreviations
Production management		
	Event management	Events from HSE Events from Maintenance Events from necessary operator tasks Conflict management
	Production orchestration (MES/MOM Functionality)	Detailed scheduling Dispatching Track & trace Performance analysis
	Integration of business systems into plant production execution (personnel Process interface/clusters interaction)	Integration of autonomous plants in site cluster Production to Business integration (from CRM(ERP) to work orders in the MES) Production to supplier integration (From ERP (Bill of Material, Recipes) to MES work orders)
Process Management		
	Process execution	Alarm Management Control loop performance Process control State based control Asset integration HMI
	Process modelling	Process analytics Embedded Analytics Process performance & KPI's Process Modelling & Digital Twin
	Operator Training Simulator (OTS)	Operator Training System (OTS)
Asset management		
	Design of equipment	Design requirements Criticality ranking (CR) Asset OEE tracking Vendor integrated improvement process Asset Standardization
	Measureability	Improve measureability Improve robustness of sensors Integrated and performing data transfer from sensor to data storage
	Asset condition Monitoring by embedded analytics	Defined digital operating window of assets Embedded Analytics Soft sensors Advance pattern recognition Asset interface to process
	Maintenance strategy	Asset strategy Maintenance requirements of assets Maintenance job execution preparation
	Maintenance execution	Digital available asset information for maintenance Digitization of maintenance job execution Replacement of human activities by robots
	IT/IIOT/OT Foundations	Asset identification in field area Asset master data in CMMS/ERP/Engineering systems available Asset operation data in structured form in datalake (UNS) Data & Systems

4.2 Horizontal dimension of the AOM Matrices

Horizontally, for each dimension described in 4.1 the transitions from one level of AO to the next, which primarily involve implementing functionalities to reduce human interaction, are detailed and categorized by subject. The mat-

rix is organized using “swim-lanes” to indicate the required process flows. Typical criteria and solutions are described. So, the AOM Matrix assists users in identifying their current level of Autonomous Operations (AO) and guides them through the necessary transitions to advance to the next AO maturity level.

The columns in Figure 3 are:

- Transition from level 2 to level 3 (in grey)
- Features required for level 3
- Transition from level 3 to level 4 (in grey)
- Features required for level 4

Production management		Transition Level 2→3	Level3 Predictive	Transition Level 3→4	Level 4 Prescriptive	Transition Level 4→5	Level 5 Autonomous
Process management		Carry out alarm rationalization to achieve 2nd level of feedback	"Predictive" level of Alarm Management (FMEA, root cause analysis) understood	Investigation and preparation of alarm and operational actions for fully state	Full state based alarm management in place	Automation of mitigation	Performance analysis does not only involve the production process and the
Asset management		Transition Level 2→3	Level3 Predictive	Transition Level 3→4	Level 4 Prescriptive	Transition Level 4→5	Level 5 Autonomous
Design of equipment	Design requirements	Develop for new assets or improve existing	Clear specifications for critical assets available (quality ensured during manufacturing)	Continue with program	Design specifications for all assets defined		
Process design of equipment	Criticality ranking (CR)	Execute/review CR for to prepare for next maturity level	CR done and understood	Execute/review CR for to prepare for next maturity level	CR updated and understood	Execute/review CR for to prepare for autonomous	
Design of equipment	Asset OEE tracking	Collect bad actors from history (CMMS)	Bad actors (FMEA) identified and prioritized, asset KPI's defined to verify the asset performance against design	Further investigate predicted upsets and prolong asset life time by design changes	(Most) asset upsets known and identified before happening		Standardized Asset adapted to process requirements and with (if necessary) vendor support. Asset lifetime and critical components are known and supervised
Process design of equipment	Vendor integrated improvement process	Start discussion with vendors for possible future improvements and support	Improvement program started	Continue with program	All critical equipment has active vendor life cycle support program in place		
Design of equipment	Asset Standardization			Investigate asset diversity and start standardization program	Asset standardization for critical assets in place		
Integr. system							
Process e		Add sensors for all critical assets to monitor integrity and reliability	Necessary condition monitoring sensors for critical assets in place	Further improve upset prediction of assets and start to standardize	Critical assets / equipment have an asset monitoring toolset to assure availability		Rotating and static assets equipped with robust sensor and/or softsensors
Measureability	Improve measureability	Add sensors for risk scenarios (leakage/upset) in unit operations	Necessary condition monitoring sensors critical for upset prediction of unit operations in place	Continue with program for further improvement of upset prediction of unit operations and start to standardize	Extra softsensors in feedback loop in place for unit operations to identify upset scenario's		Unit operations are equipped with robust sensors and/or softsensors
Process e		Define design and installation guidelines criteria for measurements/sensors and network(s)	The health status of measurements/sensors are continuously monitored	Start with anomaly detection and/or data-quality for critical and essential sensors	Anomaly detection and extended monitoring of all critical and essential sensors is in place	extend anomaly detection to all sensors including automatic maintenance notifications to repair and calibrate	Monitoring of all measurements/sensors is in place
Measureability	Improve robustness of sensors						
Process e		Integrated and performing data transfer from sensor to data storage	OT-architecture / data blueprint defined for level 1/2/3/4/5, PCS, MES, data-lake (historians), data-streams to external suppliers to be defined	Solid foundational OT-architecture in place	Enhance OT-architecture and its scalability and expandability	OT-architecture allows addition of sensors/measurements without human effort	

Figure 3: Impression of the matrices covering 3 domains.

- Transition from level 4 to level 5 (in grey)
- Features required for level 5

The AOM Matrix provides a generic description of what should be done to pursue the next level of autonomous operation. The reason this is kept generic is that many companies have different approaches and workflows. However, the development of the document showed that work areas, as well as states and transitions, are very similar.

4.3 Example

This practical example is drawn from one of the many rows in the matrix, specifically highlighting one of the aspects, in this case process control related. Imagine a chemical production company, that has been operating for years using traditional process control. Operators monitor the processes and intervene when necessary. This is the starting point - Level 2.

Transition to Level 3 – Predictive Control

The company decides to improve its process control. They implement advanced control strategies such as feedforward control and model-based control (MPC). This allows them not only to react to deviations but also to predict when a process might go off track.

➔ Result: The plant reaches Level 3. Processes are now more stable, especially during steady-state operation and load changes.

Transition to Level 4 – State-Based Automation

After this improvement, the company notices that startup and shutdown procedures still require a lot of manual intervention. They integrate their process control with **state-based automation**. This enables the system to recognize its current state (e.g., startup, normal operation, shutdown) and respond accordingly if anything changes or certain events occur.

➔ Result: The plant reaches Level 4. Most process steps now run autonomously, with minimal human involvement.

Transition to Level 5 – Full Autonomy

As a final step, the company further extends fallback strategies in case key measurement instruments fail. Think of automatic switching to backup sensors or adjusted control modes. At the same time the state-based automation can take decisions to deal with this situation and keep the plant running till a planned shutdown. Additionally, control loops become adaptive, automatically adjusting to changing conditions.

➔ Result: The plant now operates largely autonomously, even in unexpected situations. This is Level 5 – robust, self-correcting, and future-ready.

5. Conclusion and Outlook

The AOM Matrix' states and its transitions are indicative for the steps and the direction companies need to follow

to achieve their aspired level of autonomy. As we learn through time, the matrix and more particular, its transitions might have to be tweaked to represent better solutions. We count on the community of both WIB and NAMUR to provide feedback, which will enrich and enhance the matrix for our further use.

This article summarizes the joint WIB and NAMUR efforts to help end-users taking steps towards achieving a more autonomous operation and intends to inform a broader audience of our activities. With this article we like to trigger enthusiasm from you, to use the matrix, helping you to achieve higher levels of autonomy in your assets.
